Category:SimCityVarious types of data processing systems have been developed including storage systems, cellular telephone systems, and radio transmission systems. In such systems, data is transferred from a sender to a receiver via some medium. For example, in a storage system, data is sent from a sender (i.e., a write function) to a receiver (i.e., a read function) via a storage medium. As information is stored and transmitted in the form of digital data, errors are introduced that, if not corrected, can corrupt the data and render the information unusable. The effectiveness of any transfer is impacted by any losses in data caused by various factors. Many types of error correcting systems have been developed to detect and correct errors in digital data. For example, error detecting codes such as cyclic redundancy check (CRC) codes, forward error correcting (FEC) codes, and Reed-Solomon codes can be used to increase the likelihood of data recovery. The effectiveness of any transfer is also impacted by the integrity of any associated controlling logic and/or other functional aspects of the data processing system. Many types of controlling logic can introduce logic errors, further contributing to a data recovery problem. Other errors can be the result of physical failure of system components. Various approaches have been developed to address the problems associated with data transfer and logic/system errors. These approaches include storing multiple copies of data, using redundant control mechanisms, and adding various forms of redundancy to data or controlling logic. These traditional approaches are far from optimal as each generally requires more system resources (i.e., additional hardware, processing time, etc.) and often does not correct the actual error(s) but, at most, flags the error. More recently, various forms of nonvolatile memory have been developed that retain data even when power is removed. Such nonvolatile memories include, for example, flash memory. With advances in fabrication technology, integrated circuit flash memories are becoming to have high density with high performance in the areas of cost, reliability and device size. The use of a high density flash memory as a replacement for conventional hard disk drives is beginning to emerge. In particular, flash memory is expected to displace the hard disk drive as a storage device of choice in a personal computer (PC) and data communications applications. This is because flash memory is nonvolatile, providing the capability to store data (code, information, etc.) even when power is removed. It is a relatively low-cost memory technology for such applications. It also has 82138339de
