Press CTRL+L (Windows) or OPTION+⌘+L (Mac) to create a new layer above your existing layers and hide it by clicking in the layer box. You will refer to this layer throughout the following steps as your work layer. If you need to add more than one layer, you can use Ctrl+click (Windows) or -click (Mac) to create new layers instead of using the New Layer button. To add a new layer, simply click the New Layer button again (looks like a plus sign) to create a new layer above the existing ones. Figure 1-6 shows you the layers window with a red box around the (hidden) work layer and four sample layers. Notice how the lower (hidden) layer is easier to see. By hiding the work layer, you can see at a glance which layer is currently active. **Figure 1-6** Use the layers window to easily access and manage your layers.

Estimating gross national product and productivity: a brief history. This review of the use of GNP and productivity in the United States at the national level during the twentieth century attempts to consider the fact/use relationship. It attempts to give a survey of the history of the use of GNP/productivity estimates during the various periods of economic growth in this country. Prior to World War I, productivity estimates became highly correlated with GNP estimates and remained that way until the Great Depression. Since then, the two types of estimates, while somewhat correlated, have remained separate. There is no single cause which can explain this, but certain facts certainly are pertinent. After World War II, there was an attempt by growth economists to synchronize GNP estimates with the reporting of national accounts, using a method of rectifying the excess. The method of rectification was appropriate at the time, and undoubtedly did offer much insight into the theoretical construct of national accounts. However, in order to link GNP/productivity with national accounts, a sophisticated infrastructure was built up. As we move into the 1980s, there is no justification for the existence of such an infrastructure. We need to recognize that GNP estimates do not necessarily take into account the operations and results of the non-financial economy in proportion to their importance to the total national economy. We need to review the necessary infrastructures of national accounting and their theoretical basis. Before we can begin to use GNP estimates we must ask why such estimates have been developed and why they are currently being used. [group.table.properties](#)

Aberrant expression of multiple tumor genes in retinoblastoma. The incidence of retinoblastoma has doubled in the United States since the 1970s. The most commonly used treatment modality for retinoblastoma is enucleation of the tumor. Despite this aggressive treatment, there is a 10% to 15% rate of tumor recurrence. The major known risk factors for tumor recurrence are bilateral disease and tumor size greater than 3 mm. On the basis of these data, it has been suggested that multifocal retinoblastoma is an independent risk factor for tumor recurrence. We have developed a novel expression microarray to investigate tumor expression profiles. Using this microarray, we compared gene expression profiles between embryonal retinoblastoma and normal retina to identify tumor-specific gene expression patterns that might serve as prognostic indicators. In addition to the presence of the most common risk factors for tumor recurrence, we found that the expression of multiple tumor genes was also significantly elevated in retinoblastoma. The tumor-specific expression patterns described here may help to identify individuals at risk for disease recurrence in patients with unilateral retinoblastoma, to identify individuals at risk for metastatic disease, and to better understand the molecular biology of retinoblastoma.Q: What is the difference between renderings and econometrics? A: You can think of an econometric model as a mathematical description of how the world works. To put it another way, it's a "theory" about the world. The graphical representation of this theory in, say, the form of a graphic, is a "rendering". In modelling econometrics, the rendering is an accurate and informative representation of the theory; the theory describes how the world works, and if we are happy with the accuracy and informativeness of the rendering, we have a "good" econometric model. So to say that renderings are "statistics", or "econometrics", is confusing; these terms are intrinsically statistical, and it would be as sensible to ask whether physics is a statistic (because it's all about numbers). What is a statistic? A good rendering, in contrast, can be seen as descriptive statistics, as they should try and convey all the useful information in the data, and they should not be prone to "bias" (so
